

THE DEVELOPMENT OF BASIC PHYSICAL FEATURES OF CZECHOSLOVAK ADULT POPULATION IN 1955—1965

V. FETTER, J. SUCHÝ

The big concentration of adult population during The National Spartakiade nation-wide organized physical exercises offers a good occasion for a state-wide anthropological research. I National Spartakiade took place in 1955, II in 1960 and III National Spartakiade took place in 1965. In 1963, V. Fetter referred about the changes during the first five years.*¹) The anthropological research of the participants in III National Spartakiade took place in dressing places of the Strahov's Spartakiade Stadium in Prague in the last days of June and the first days of July 1965. The investigation was carried out by the Anthropological Department of the Faculty of Natural Sciences of Charles' University in Prague, under the leadership of Professor V. Fetter and by the Anthropological Laboratory of the Pedagogical Faculty of Charles' University in Prague, under the leadership of Assistant Professor J. Suchý, in cooperation with the members of the Czechoslovak Anthropological Society.

Besides the personal data of participants, concerning place of birth, place of residence, age, occupation, sports-activity, some body measurements were taken: height, weight, circumferences of the chest and neck, and three other trunk dimensions. The circumferences were measured, as it does not require any special anthropological apparatus and gives a good knowledge of circumferential dimensions of the trunk which is important for industrial needs and for medical investigations, particularly for the obesity research.

Mechanical processing of data was done thanks to the understanding of the computing department of The State Planning Commission. The scientific programme of mathematical analysis was accomplished by Dr. Robek, the scientific worker of this Commission.

In this work the analysis of basic physical characteristics like height, weight and circumference of the chest of men and women is given, both from Czech lands and Slovakia. The investigation during III National Spartakiade did not bring so numerous

results as the investigation during II National Spartakiade, because the time of investigation was much shorter, and only ten persons were permitted into the cloakrooms to carry out the investigation, so that it was possible to form three measurements groups, at most. Also the time for investigation was very short, because it could take place only between the arrival of gymnasts to the dressing places and their departure for the exercising field.

Besides, the number of investigated features was twice as large as the number acquired during II National Spartakiade.

The greatest number of investigated persons, both men and women, originated from Czech lands, and the most interesting phenomenon — continuous prolongation of physical fitness and activity of adult population was observed. Some active participants in the age over 65 years were measured, both men and women. In total, 5187 persons were measured, i.e. 2148 men and 3039 women. It was not possible to measure older age groups from Slovakia, because from this country there came mostly members of younger age groups.

THE BODY HEIGHT

The values of body height ascertained during I National Spartakiade were compared with the values ascertained by J. Matiegka in 1895, and it was found that the body height of our population had increased considerably in the course of the last 60 years. For the present this phenomenon is one of the most important anthropological problems, and it is characterised as the secular factor. According to the Mexican anthropologist Genoves, the phenomenon involved is world-wide and shows the average increase of 1 cm of the body height in ten years. Most important in our investigation is the age group from 18 to 19 years, when the ontogenetic dynamics of growth is considerably slowing down and completed. The difference of the body height in this age group of men between II and III National Spartakiads is 0.6 centimetres, which roughly corresponds with the situation of Genoves, i.e. the average growth increases by 1 centimetre in every ten

CS = National Spartakiade

years. In other age groups the values of body height are equal or somewhat higher in comparison with the values ascertained at II National Spartakiade. The average of the body height in the age group from 25 to 39 years, which represents the fully adult population without changes of growth, and without involution caused by age, increased by 0.4 centimetre. During II National Spartakiade the ascertained average height was 173.5 centimetres and at III National Spartakiade 173.9 centimetres. The corresponding deviation at III National Spartakiade is 5.19 centimetres and at II National Spartakiade 6.54 centimetres. The

increase of 0.4 centimetre again corresponds roughly with the expected value according to Genoves. When compared with I National Spartakiade, the increase is 0.7 centimetre, which is approaching again to the values expected. If we follow the various width of the whole in individual height classes, we can observe a larger homogeneity at III than at II National Spartakiads. This can be observed in corresponding deviations which at III National Spartakiade are generally lower than at II National Spartakiade, with the exception of the age groups 18-19 and 50-54 years, which is the result of greater variability in the period of termi-

nating growth and of the beginning involution of the age group 50—54 years.

During II National Spartakiade, gymnasts in the age group from 55 to 59 years were measured, at III National Spartakiade the age group from 60 to 64 years is still quite large, and even certain number of gymnasts over 65 years of age was measured. This ascertainment is an evident demonstration of the prolongation of active age, which is probably connected with the prolongation of the average length of life.

Slovak participants were measured in smaller groups than the case was during II National Spartakiade. Nevertheless, considerable results were noticed in age groups which are the main object of anthropological investigation, i.e. from 18 to 34 years. In these age groups, higher values were found in comparison with those, found during II National Spartakiade. Similar to Czech lands, the average body height increased in the age group from 18 to 19 years. In the joint groups from 25 to 39 years of age the average body

height increased from 171.1 centimetres at II National Spartakiade to 172.1 centimetres at III National Spartakiade. In comparison with I National Spartakiade, the difference is equal to that in the Czech lands, i.e. 0.7 centimetre.

The values of body height acquired by the measurement of women in Czech countries in all age groups of III National Spartakiade are higher than the values of II National Spartakiade. In the age group from 18 to 19 years this difference, in the period of five years, is 1.1 centimetre, which surpasses the value expected by Genoves. Also the total average of women height in the joint age group from 25 to 39 years increased by 1.1 centimetre, because the average found out at II National Spartakiade was 161.0 centimetres, and at III National Spartakiade 162.1 centimetres. In comparison with I National Spartakiade, i.e. during ten years the difference is 1.6 centimetres. The measurement of Slovak women in the age group from 18 to 19 years a considerable increase of body height re-

veals, similar to that in the age group from 20 to 24 years. In the other age groups the values are approximately equal to those of II National Spartakiade. The total average 160.1 centimetres in the joint group 25–39 years is almost equal to that of II. National Spartakiade, i.e. 160.2 centimetres. In comparison with I National Spartakiade the average body height of Slovak women increased by 1.4 centimetres, which makes an increase a bit higher than the value expected according to Genoves.

CS = National Spartakiade

THE BODY WEIGHT

In Czech lands a considerable increase of body weight in all age groups of men could be observed. The highest values are to be found in the age group from 35 to 39 years, i.e. 79.4 kilograms. In other age groups, gradual decrease of body weight is observed, both in older and younger age groups. In older age groups it decreases gradually till the value of 74.5 kilograms in age group of men from 60 to 64 years. In younger age groups the average of weight is decreasing up to the value of 69.9 kilograms in the age group from 18 to 19 years. On the whole, the body weight of men in the age groups from 25 to 34 years does not

change. The general course of the weight curve shows the regular phenomenon which has the corresponding tendency both during II and III National Spartakiads.

In comparison with I National Spartakiade the tendency of the weight curve is similar to that of II and III National Spartakiads. At the beginning it has a sharp course and it reaches the top one age group sooner than during II and III National Spartakiads. Its course gradually decreases from the top in the direction to the higher age groups. If the extreme values of variational width of weight at III National Spartakiade are observed, it may be seen that the minima of all age groups are considerably higher than at both previous Spartakiads. The lowest value of the minimum weight at I National Spartakiade is 49 kilograms, at II 47.5 kilograms and at III National Spartakiade 57 kilograms. On the contrary, the values of the maximum at both previous Spartakiads are higher than at III National Spartakiade where the maximum weight

CS = National Spartakiade

was 105 kilograms. At I National Spartakiade the maximum weight was 107 kilograms and at II 110 kilograms. From the afore-mentioned facts can be inferred that the resulting average of weight was not influenced by the maximum weight.

The increase of the average of the body weight is to be taken into consideration when determining the limits of obesity and in industrial questions, especially when calculating the weight-load of the transport means, motorcars, and everywhere where the body weight must be considered.

A similar sort of situation is with Slovak men, too, where in the age groups where the measurement was possible, the values are higher than during both previous Spartakiads. The average body weight in joint age groups from 25 to 39 years is in Slovakia 72.7 kilograms, and is so higher than that ascertained during I National Spartakiade, i.e. 71.6 kilograms, and during II National Spartakiade, i.e. 71.4 kilograms.

CS = National Spartakiade

The weight of women increases continuously since 18 to 50 years. The higher age groups were not yet investigated during the Spartakiads. The greatest increase of weight is in age groups from 20 to 30 years. Then the increases of weight are lower, but regular. When comparing the body weight of women during III National Spartakiade with the weight ascertained during the Ist and IInd National Spartakiads, an increase can be observed in all the age groups, as well as it was ascertained during the measurement of men. In the joint groups from 25 to 39 years, the value of women's body weight in Czech lands is 64.9 kilograms, which is 1.4 kilograms higher than the value ascertained during II National Spartakiade.

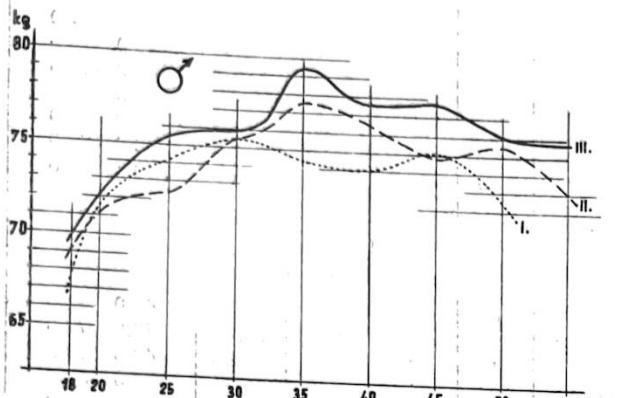

FIG. 1
Body weight — Bohemia, Moravia, men
I. — 1955, II. — 1960, III. — 1965.

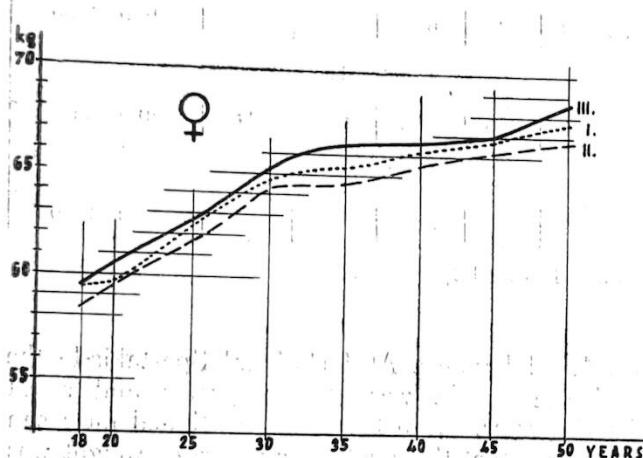

FIG. 2
Body weight — Bohemia, Moravia, women
I. — 1955, II. — 1960, III. — 1965.

Groups of Slovak women are sufficiently numerous in the first and the second age groups. When taking into consideration the small number of cases, the same phenomenon as was observed with the measurement of the gymnasts from Czech lands, i.e. the gradual increase of body weight in higher age groups, may be registered. The average body weight ascertained by the measurement of Slovak women in joint age groups from 25–39 years remains nearly without changes, i.e. 60.7 kilograms at II Spartakiade and 60.5 kilograms at III National Spartakiade.

THE CHEST CIRCUMFERENCE

Similarly as with the body height and body weight, also with the circumference of chest in all age groups of men from Czech lands a considerable increase of values of this feature can be found. From the starting value of 91.9 centimetres in the age group from 18 to 19 years, the circumference of chest of men from Czech lands increases considerably till the age group from 40 to 44 years. Then the values are nearly without change up till 60 years. In joint age groups from 25 to 39 years the average circumference of men's chest from Czech lands is 98.3 centimetres. This value is by 2.9 centi-

The same phenomenon was observed when men from Slovakia were measured. From the starting value of 90.4 centimetres in the age group from 18 to 19 years a fast increase up till the value of 97.1 centimetres in the age group from 30 to 34 years can be observed. In joint age groups from 25 to 39 years, the circumference of chest of the

gymnasts from Slovakia is 96.0 centimetres at III National Spartakiade. In comparison with II National Spartakiade, it is 3.2 centimetres higher.

CS = National Spartakiade

The chest circumference of women from Czech lands is also in all the age groups higher at III National Spartakiade than at I and II National Spartakiads, with the exception of the age group from 18 to 19 years at II National Spartakiade. The considerable increase of the value of this phenomenon seen from the view-point of the secular factor emerges best in the comparison of the values from I National Spartakiade, i.e. in the course of ten years. The circumference of the chest of women increases in the direction to the higher age groups. In the joint age groups from 25 to 39 years, the value of circumference of the chest of women from Czech lands at III National Spartakiade is 89.7 centimetres, i.e. 2.4 centimetres higher than at II National Spartakiade (87.3 centimetres). The same difference is in comparison with I National Spartakiade.

In conformity with this fact, the increase of circumference of the chest of Slovak women in the direction to the higher age groups may be observed. In the joint age groups from 25 to 39 years, the value of circumference of the chest of Slovak women at III National Spartakiade is 87.2 centimetres. This value is 0.6 centimetre higher in comparison with the value from II National Spartakiade.
