CHARACTERISTICS OF THE BRONZE AGE
OSTEOREOLOGICAL FINDS FROM THE LOCALITY
VELIM NEAR KOLÍN

ABSTRACT — The archaeological research of the Bronze Age locality "Skalica" in Velim near Kolín (in central Bohemia) has resulted in the uncovering of 102 "objects" (pits, graves, heaps of waste and debris, etc.) and has yielded so far twenty-five human and animal skeletons. Some research features contain pebbles, small and big stones, scattered human and animal bones and parts of skeletons, sherds, and also occasional finds of bronze and gold. The single and agglomerated finds of human and animal bones are situated irregularly or are randomly dumped. On the osteological material (amounting to 50 thousand items of human and animal bones) we can follow their smashing, crushing, breaking and splitting, rare operations (cuttings, etc.), or cases of charring and cremating of bones. The traces left with the eating of human and animal meat, as visible on the osteological finds can be explained, only as documents of anthropophagy. The extraordinary amount of human and animal remains from earlier and contemporary excavations will be subjected to further studies to explain the rites connected with human and animal sacrifices in the Bronze Age.

KEY WORDS: Bronze Age — Central Bohemia — Anthropophagy.

FIGURE 1. Examples of spiral fractures of broken distal parts of humeri of various individuals.
J. Hrál and M. Vávra from the Prague Archaeological Institute of the Czechoslovak Academy of Sciences in cooperation with Z. Sedláček from the Kolín Museum have started a rescue research of the "Balka" Bronze Age locality in Velim. The work of the archaeologists is hindered by the earthmoving operations in full swing. Since the year 1964, 103 various pits have been discovered at the site, yielding twenty-five human and animal skeletal burials (Hrál et al. 1980). As this research is subordinated to the concrete needs of the housing construction, it is impossible to make systematic excavations of the individual pits. For this reason the osteological material may be assessed only preliminarily, as the excavation of some of the pits has not yet been completed. With this preliminary information I would like to characterize the find circumstances of the osteological material and to determine the ways of violently damaging the human and animal bones.

In the individual pits we find large agglomerations of smaller and bigger stones, small pebbles, scattered human and animal bones and parts of

skeletons, but also pottery sherds with sporadic finds of bronze or golden artifacts or their fragments. The finds of human and animal bones are isolated or in irregular agglomerations, in agglomerations or randomly thrown away. The bones have been broken, fragmented, crushed in various ways, split longitudinally or broken transversally. But one thing is clear, the spiral fractures can be made only with fresh bones, containing organic material. They prevail in human long bones (Fig. 1) and in animal long bones (Fig. 2), i.e. in bones containing marrow. Longitudinal splits or small cones from various bones (Fig. 3). On some bones we can see fine fragments cuts (Fig. 4). At places of the attachment of tendons, the cuts have sometimes the character of deep notches (Fig. 5). Exceptionally appear also burnt (grey in low) or charred bones (black) (Fig. 6) from the most varied parts of human skeleton, mostly of human bones. More frequent are the hammered human and animal bones (Fig. 7, 8) and broken mandibular branches, as consequence of separating the mandible from the skull (Fig. 9). We can find interesting damage on the — teeth — crowns (Fig. 10). Thrown are a split longitudinally, in the middle of the teeth, transversally to the middle of the crown, or over the entire surface of the teeth, and only the root in the socket remains. Teeth damaged in this way appear only in human remains, regardless of the age or sex of the deceased, i.e. in skeletal remains of children and adults alike. In certain pits appeared also drilled animal teeth (of Canis fam.). (Fig. 11). Quite exception-
probably older, the object No. 23 was excavated later. This presumption seems to be supported also by the absence of the left arm bone of the deceased (Fig. 14), probably lost during the excavation of object No. 23. Anyhow, all these remarkable finds circumstances remain unanswered in several respects. There is some analogy in the find circumstances at the Bronze Age site in Čeřavy near Blutina. In the early fifties an extensive research was launched there (Tíhelačka 1959, 1961, Jelinek 1951, 1954). The excavations restarted in the year 1983. The osteological finds at Čeřavy are more numerous, the human and animal remains were found in a variety of positions, there were complete and incomplete skeletons, or parts of split, broken, charred or burnt bones. The position of the bones varies, ranging from randomly dumped, or in crumbled, prostrate or in prone positions. The animal bones were isolated or dumped together with human bones, sherd and bronze objects.

The Blutina and Velim localities have a number of common characteristics, making them both quite exceptional. These features present also a number of problems and enigmas. The new rich finds of human remains in Velim enable the solution of the key problem of the social development of the Bronze Age in Central Europe: What happened at the sites one to two thousand years ago, to what extent can we speak of human and animal sacrifices, which individuals were sacrificed and under what conditions, in what form, when and to what extent existed anthropophagy, and other problems that will appear in the course of the research. The great number of human and animal skeletal remains will be subjected to further study to explain the problems connected with ritual life in the Bronze Age.
